AIBOOMI STARTUP WEEKEND · PROBLEM

Nowhere to park. Nowhere to charge.

At the Kerala Startup Mission in Kalamassery, 15 surface bays are full by mid-morning, with no chargers. Drivers circle, park on the road, or leave.

474 real complaints

From Reddit, forums and news across Kozhikode, Kochi, Kerala and India, collected with SerpAPI. Fights over spots, overcharging, apartments with no EV charger.

Who cares: site owners with no spare land, drivers doing two errands (park, then charge), and fleets that will need unattended depots.

INSIGHT · WHY NOW

The tower exists.
The brain doesn't.

Hardware is solved

AutoDock AI (Kozhikode) already builds rotary towers with a charger in every bay. In our model a 20-pallet tower stands on 2 parking bays.

Every car is a set of decisions

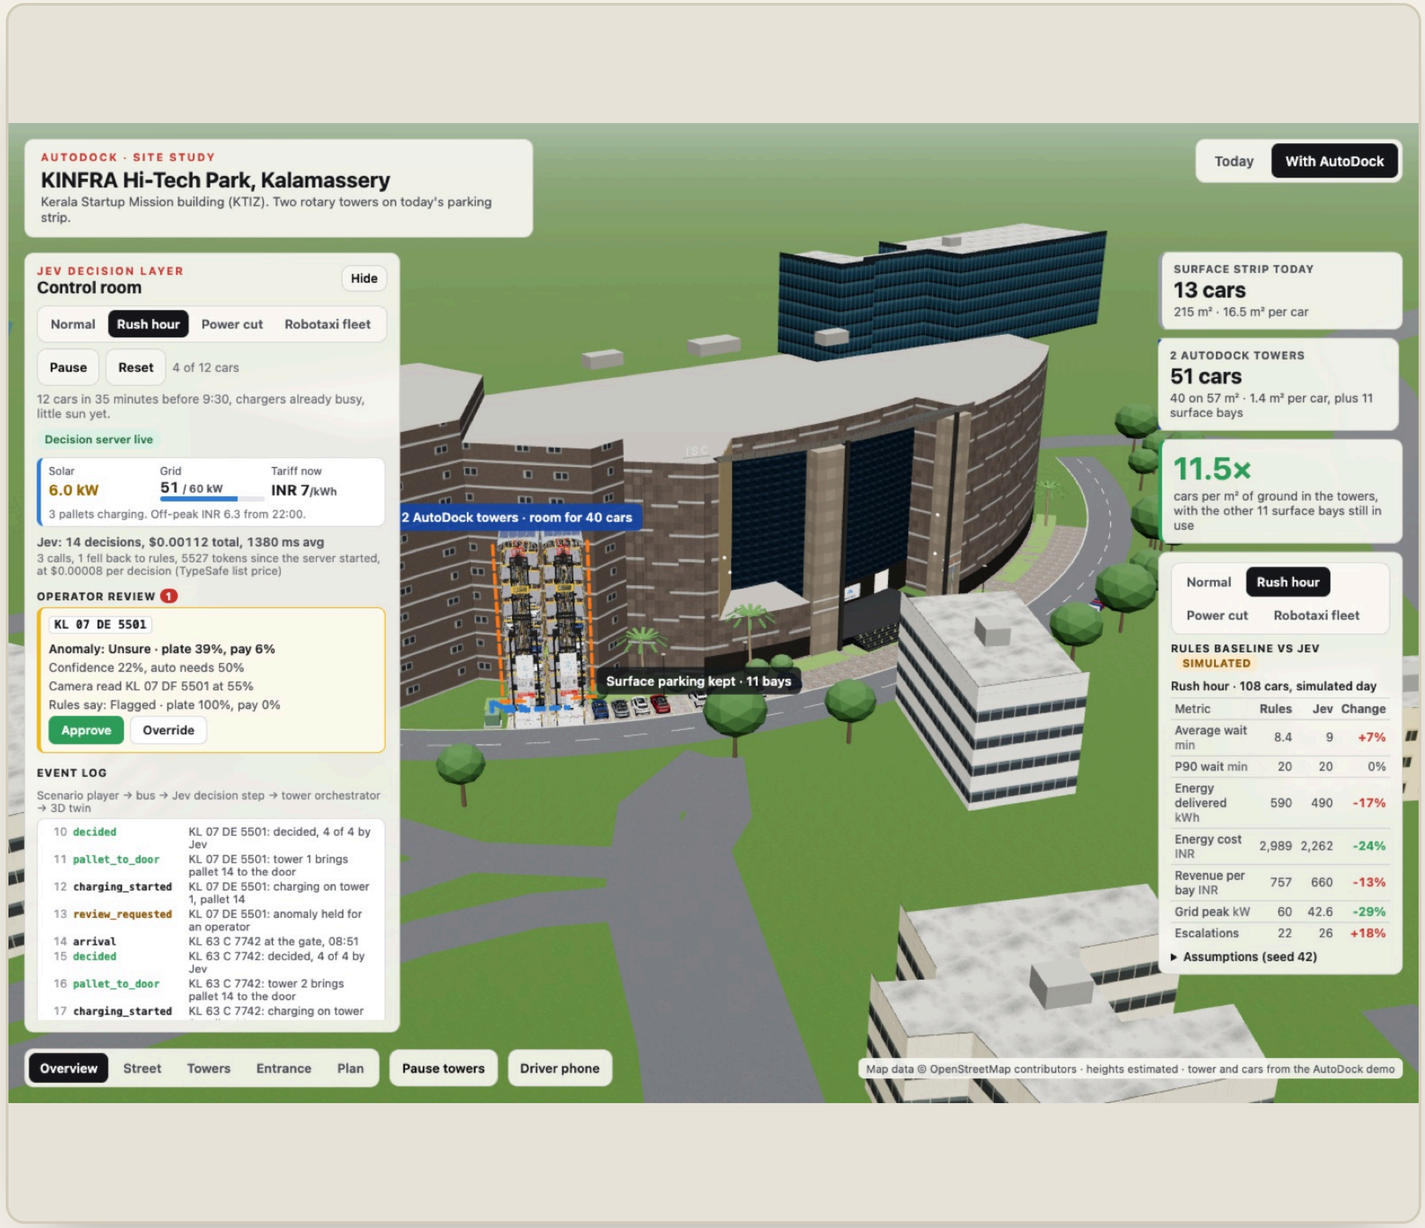

Which pallet, charge now or wait for solar and off-peak, what price, is this the right car and is it paid for. Rules get these wrong at the edges; people can't watch every car.

Why now: typed, calibrated AI

TypeSafe's Jev returns typed answers with a calibrated confidence in about half a second, for about **$0.00008 a decision**. Cheap enough to decide on every event, and honest enough to ask a person when it isn't sure.

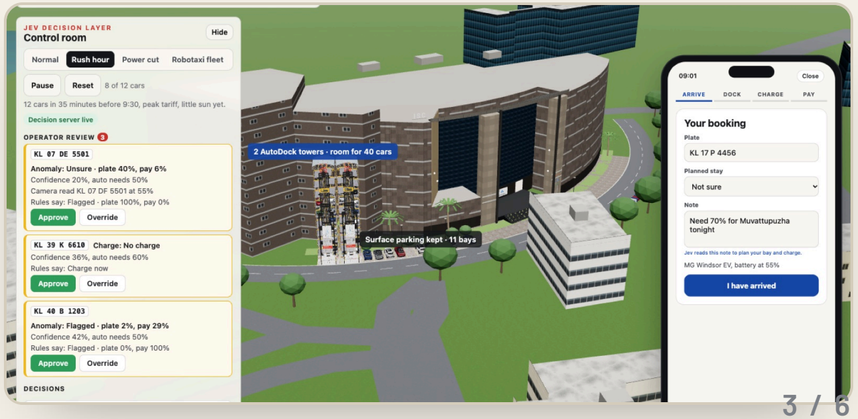

Why now: the grid

More EVs than sockets, and the site's grid connection is the bottleneck. Robotaxi fleets are scaling in the US, and need depots that run unattended.

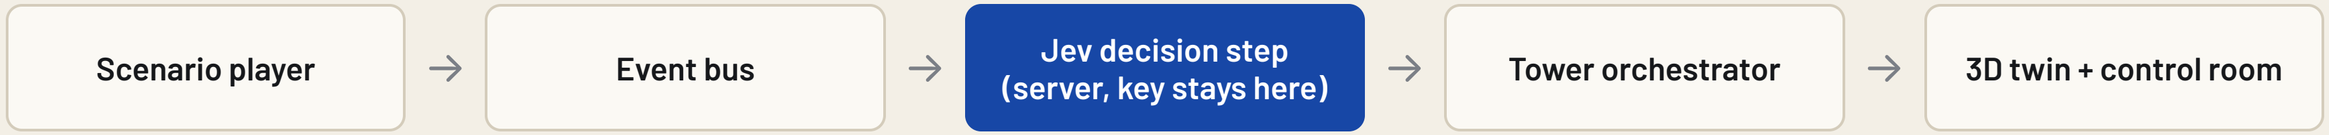

Jev decides.
It asks when unsure.

- 3D twin of the real site, two towers on 4 of 15 bays: **40 cars on 57 m²**.
- Per car: bay, charge plan, price, plate and payment checks, each with Jev's confidence.
- Unsure charge or anomaly calls go to the **operator queue**. Here: a camera misread Jev wouldn't guess on.
- Solar and grid flows, live kW gauge, Jev cost counter, event log.
- Driver phone: arrive, dock, charge, pay by UPI (mock).

TECH ARCHITECTURE

One Jev request per car.
Code owns the rest.

Five judgments, one call

- **Bay:** Choice over 4-6 pallets code proposes
- **Charge:** Choice (now, solar, off-peak, none)
- **Price:** Score, demand 0-3, mapped to a tier
- **Plate, payment:** two Nouls (probabilities)

Confidence counts options with the same outcome together: indifference between equivalent pallets is not doubt.

Guardrails

- Rules fallback on any error or timeout, same interface
- Flagged plate or payment always reaches a person
- Audit log of every decision and its confidence
- 52 tests; seeded simulator for rules vs Jev

React 19 · React Three Fiber · zustand · Vite · Node 25 · @typesafe-ai/sdk (jev-latest) · OpenStreetMap · SerpAPI

VALUE · GO TO MARKET

Same rush hour, rules vs Jev SIMULATED

RUSH HOUR, SEED 42	RULES	JEV
Grid peak	60 kW	**42.6 kW (-29%)**
Energy cost	₹2,989	**₹2,262 (-24%)**
Missed anomalies	0	**0**
Sent to an operator	22	26
kWh delivered	590	**490**

Synthetic day, illustrative tariffs and behaviour; not a measurement. Jev wins on grid and energy cost, and sells less energy. Full table in the repo.

Who pays

Site owners and operators: a per-session fee, a per-bay software subscription, a margin on energy, and a revenue share with the landowner.

How we reach them

Through AutoDock AI as the hardware partner. First a Kerala pilot site (KSUM / KINFRA style campuses), then Kochi, Trivandrum and Kozhikode; fleets and robotaxi depots next.

Ready to send

Non-binding LOI drafts for AutoDock AI (shadow pilot) and a site owner (survey and proposal).

ROADMAP · RISKS

From simulation to a real tower.

Next

- **4 weeks:** integrate with AutoDock's tower controller on recorded events.
- **8 weeks:** shadow pilot at one Kerala site: Jev logs what it would decide, controls nothing.
- Calibrate thresholds on real outcomes; tune for each site's grid and tariffs.
- Live pilot under a separate agreement if the shadow results hold.

Risks, stated plainly

- Our numbers are simulated; real behaviour may differ.
- Depends on a hardware partner and site approvals (grid, fire, structural).
- Jev's calibration checked only on synthetic cases so far.
- Demo 3D models come from AutoDock's demo; permission needed for public use.

> *The ask: a pilot site, an introduction to AutoDock AI's team, and mentors who have run EV or parking operations.*
